## Worksheet 22

TITLE Linearization: Analyzing Quasi-Linear Systems of ODEs
CURRENT READING Blanchard, 5.1

## Homework Assignments due Monday November 2

(* indicates EXTRA CREDIT)
Section 5.1: 3, 4, 5, 8, 18, 20*.
Section 5.3: 2, 9, 12, 13, 14, 18*.
Chapter 5 Review: 1, 2, 6, 7, 8, 9, 11, 12, 26, $27^{*}$.

## SUMMARY

We shall begin our analysis of non-linear systems using a technique called linearization which transforms the behavior of nonlinear systems of ODEs back into our now familiar analysis of linear systems of ODEs. Remember your Taylor Approximations!

## 1. The Van der Pol Equation

An important nonlinear system of ODEs which occurs in Physics is the Van der Pol Equation for $x(t) x^{\prime \prime}+x-\left(1-x^{2}\right) x^{\prime}=0$ which can be written as a non-linear system as

$$
\begin{aligned}
& \frac{d x}{d t}=y \\
& \frac{d y}{d t}=-x+\left(1-x^{2}\right) y
\end{aligned}
$$

Below is the direction field and phase portrait for the Van der Pol system. What do you notice? (HINT: Locate the stationary point(s)!)

Q: What happens to solutions that start near the origin at $(0,0)$ ? What about solutions that start (relatively) far away at $(3,3)$ ?
A:

Here is a close up of the phase portrait near the point $(0,0)$

Q: What can we say about the stationary point at $(0,0)$ of the Van der Pol system? A:

## EXAMPLE

Let's use the technique of linearization to explain the behavior near the origin of the Van der Pol system. Suppose $x$ and $y$ are close to 0.1 in size, then the nonlinear term $x^{2} y$ will be close to $\left(0.1^{3}\right)$ in magnitude, much $\qquad$ then either $x$ or $y$.

We can therefor write a linearized version of the Van der Pol system which looks like

$$
\begin{aligned}
& \frac{d x}{d t}=y \\
& \frac{d y}{d t}=-x+y
\end{aligned}
$$

which when written as a matrix looks like $\frac{d \vec{x}}{d t}=\left[\begin{array}{cc}0 & 1 \\ -1 & 1\end{array}\right] \vec{x}$ where $\vec{x}=\left[\begin{array}{l}x(t) \\ y(t)\end{array}\right]$

## Exercise

Find the eigenvalues of the linearized Van der Pol system and use this information to classify the stationary point at $(0,0)$.

## 2. The Linearization Process

## RECALL

## Definition: Jacobian matrix

The derivative matrix (usually called the Jacobian) of a vector function $\vec{f}: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$ is the matrix consisting of the $n$ partial derivatives of each of the $m$ co-ordinate functions arranged so that the rows of the matrix are exactly gradient vectors of each coordinate function. The Jacobian has $m n$ entries where $J_{i, j}=\frac{\partial f_{i}}{\partial x_{j}}$. In other words,

$$
J(\vec{x})=\left[\begin{array}{cccc}
\frac{\partial f_{1}}{\partial x_{1}} & \frac{\partial f_{1}}{\partial x_{2}} & \cdots & \frac{\partial f_{1}}{\partial x_{n}} \\
\frac{\partial f_{2}}{\partial x_{1}} & \frac{\partial f_{2}}{\partial x_{2}} & \cdots & \frac{\partial f_{2}}{\partial x_{n}} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial f_{m}}{\partial x_{1}} & \frac{\partial f_{m}}{\partial x_{2}} & \cdots & \frac{\partial f_{m}}{\partial x_{n}}
\end{array}\right]
$$

Consider the general form of a 2-dimensional nonlinear system of 1st order ODEs

$$
\begin{aligned}
& \frac{d x}{d t}=f(x, y) \\
& \frac{d y}{d t}=g(x, y)
\end{aligned}
$$

This can also be thought of as $\frac{d \vec{x}}{d t}=\vec{f}(\vec{x})$. Clearly in this case $f: \mathbb{R}^{2} \rightarrow \mathbb{R}^{2}$ so the Jacobian matrix $J$ for $\vec{f}(\vec{x})$ would be a $\qquad$ .

We can always use Taylor's Theorem for Vector-Valued Functions to approximate the function $\vec{f}(\vec{x})$ near a point $\vec{x}_{0}$ by saying

$$
\vec{f}(\vec{x}) \approx \vec{f}\left(\vec{x}_{0}\right)+J\left(\vec{x}_{0}\right)\left(\vec{x}-\vec{x}_{0}\right)+\ldots
$$

This will be extrememly useful if the nonlinear system has a fixed point at the point ( $x_{0}, y_{0}$ ) (also known as $\vec{x}_{0}$ ) because then we will be able to analyze a linear system of the form

$$
\frac{d \vec{x}}{d t}=J\left(\vec{x}_{0}\right)\left(\vec{x}-\vec{x}_{0}\right)
$$

instead of the original nonlinear system
In fact, usually the change of variables $\vec{u}=\vec{x}-\vec{x}_{0}$ will be made and we will be analyzing the system

$$
\frac{d \vec{u}}{d t}=J\left(x_{0}, y_{0}\right) \vec{u}, \quad \text { where } \vec{u}=\left[\begin{array}{l}
u \\
v
\end{array}\right]=\left[\begin{array}{l}
x-x_{0} \\
y-y_{0}
\end{array}\right]
$$

where the fixed point will now be at the origin of the $(u, v)$-system instead of at $\left(x_{0}, y_{0}\right)$ in the $x y$-plane.

## GroupWork

Consider

$$
\begin{aligned}
& \frac{d x}{d t}=-x+x^{3} \\
& \frac{d y}{d t}=-2 y
\end{aligned}
$$

Identify and then classify all the equilibria of the non-linear system of ODEs, using the Linearization Process. (HINT: calculate the Jacobian, evaluate at each equilibria, compute the eigenvalues and classify the equilibria)
