(02.03.97) Newton's Method and Secant Method

Newton's Algorithm

Bisection and False Position are both **globally convergent** algorithms, because, given a bracket which contains a solution, they both will find the solution, eventually.

Newton's Method (and the Secant Method) is very different from these methods, in that instead of needing a bracket where the solution exists [i.e. two function values whose product is negative] one needs a **single** guess of the solution, which has to be "close" to the exact answer, in order for these **locally convergent** to get the solution.

Derivation of Newton's Method

Write down the first 3 terms of a Taylor expansion of $f(x)$ about the point $(p_0, f(p_0))$

Evaluate this function at the root, the point $(p_1, 0)$ and solve for p_1

This is the iterative step for Newton's Method

Pseudocode for Newton's Method

Example

Consider the function $f(x) = x^2 - A$, where $A > 0$

Compute the Newton iterative step using the above function $f(x)$

Simplify it, so that it look like $x_{n+1} = \dfrac{x_n + A/x_n}{2}$. Recognize this iteration?

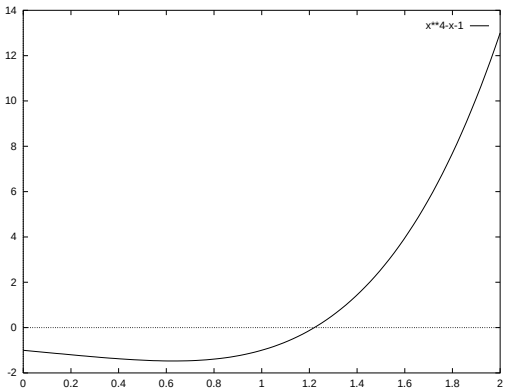
Secant Method

The secant method is very similar to Newton's method, except that instead of actually computing the derivative, one approximates it using a difference quotient. This ends up in making the iterative step look identical to the one for False position.

Secant Method iterative step

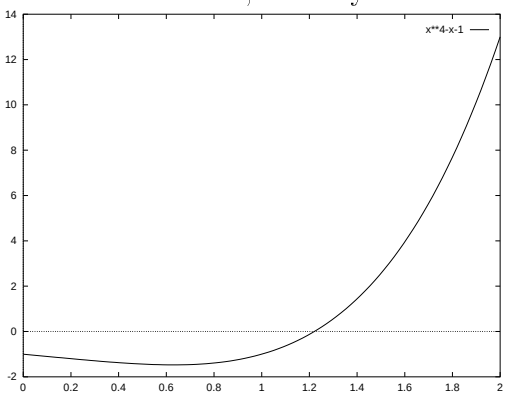
If the iterative step is identical to False Position, how come the Secant Method is not just called the False Position method? Look at the picture...

Secant Method, visually



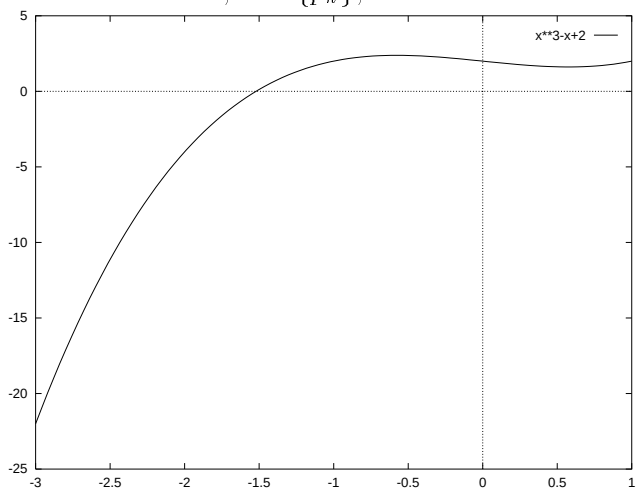
False Position Method, visually

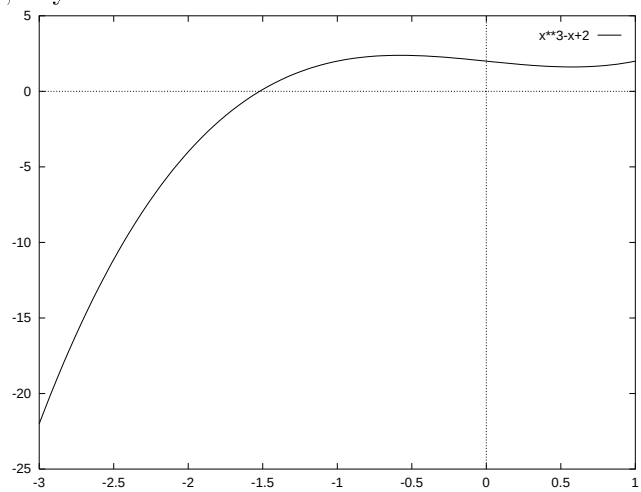
Now, let's recall what False Position look like, visually...



Example

Consider the following function $f(x) = x^3 - x + 2$. Draw on the graph the set of approximations to the zero, i.e. $\{p_k\}$, due to Newton's Method, if you start at $x = 1$





You may want to also indicate how Bisection, False Position and Secant would produce their corresponding approximations to the solution also. (Use different colored pens, or different letters.
